CAT SCRATCH DISEASE
(Bartonella henselae infection)

What is Cat Scratch Disease (CSD)?
Cat Scratch Disease (CSD) is an infection caused by Bartonella henselae bacteria. In healthy people, it most often causes a swollen lymph node and mild illness. The domestic cat is the animal that carries the CSD bacteria, which are transmitted between cats by the cat flea.

How do people get CSD?
People can get CSD when they are bitten or scratched by a cat with a flea infestation. The feces of cat fleas contain the CSD bacteria. A person can become infected when the flea feces enter a break in the skin during a cat scratch or bite. Direct contact with cat fleas is unlikely to be a cause of infection. Infected cats usually do not look sick.

What are the symptoms of CSD?
The most frequent symptom of CSD is a swollen lymph node, usually occurring in the head, neck, or arms. It may take one to four weeks for lymph node swelling to appear after contact with an infected cat. Swelling, redness, and pain that occur at the bite/scratch site within one to two days is probably not CSD. Swollen lymph nodes often take 2 to 4 months to return to normal, with or without antibiotic treatment. In addition, people with CSD can have headache, fever, fatigue, and a poor appetite. Rare complications of CSD in people with normal immune systems include inflammation of the eyes, heart, or brain. People with compromised immune systems, such as organ transplant patients, cancer patients, or those with HIV/AIDS, are more likely to have severe illness if infected with the CSD bacteria.

How is CSD diagnosed and treated?
If you have been scratched or bitten by a cat, and develop symptoms that look like CSD, your doctor may order a blood test to help determine if you have CSD. Your doctor will decide whether you will need to be treated with antibiotics.

How common is CSD?
About 22,000 to 24,000 cases of CSD occur in the United States every year and about 2,000 people are hospitalized as a result of the infection.

What can a person do to prevent CSD?
About 40 percent of cats carry the CSD bacteria at some time in their lives. However, young cats and kittens are more likely than older cats to be infected and pass the bacteria on to people. To prevent CSD, people should:
• use flea control products on pets
• wash hands after handling, petting, or playing with a cat
• avoid rough play with cats (especially kittens)
• adopt mature cats (one year of age or older)
Where can I get more information about CSD?
The U.S. Centers for Disease Control and Prevention has information available at their website [http://www.cdc.gov/healthypets/diseases/cat-scratch.html](http://www.cdc.gov/healthypets/diseases/cat-scratch.html).
